SFT – Technical Product Definition (For CTO / Engineering Team)
System Overview, Functional Logic & Architecture Intent

---

1. Platform Vision

SFT is designed as a **Commercial Real Estate Transaction Operating System**.

The goal is not to build a listings portal.
The goal is to digitize the entire RE workflow — from requirement generation to transaction closure — and eliminate fragmented tools (Excel, WhatsApp, PDFs, emails).

The platform should function as a **multi-sided network platform** connecting:

- Occupiers (companies / startups / GCCs)
- Brokers
- Landlords / Developers
- Coworking operators
- Consultants (legal, project, design)

Each module represents a stage of the transaction lifecycle and must share a common database layer.

Core Principle:

Data should be entered once and reused across all modules.

---

2. System Architecture (High Level)

The platform should be built around a **central property + requirement data layer**.

Core Databases:

1. Property Inventory Database
2. Requirement Database
3. Transaction/Deal Database
4. Media & Asset Database
5. User & Organization Database

All modules (Explore, Analytic, Konnect, Studio) read and write to the same structured data.

This is critical — modules are not separate products.
They are different interfaces to the same system.

3. Module Definitions

A. EXPLORE (Availability & Matching Engine)

Primary Function:
Real-time discovery of available spaces.

Key Technical Objectives:

- Maintain live property inventory
- Map supply to demand
- Structured search & filtering

Core Components:
• Property listing ingestion (manual upload + API integrations)
• Availability status tracking
• Requirement matching engine
• Filters (location, area, budget, building type, furnishing, operator, floor plate, etc.)
• Admin dashboards for updating inventory – TBD

Critical Requirement:
Inventory must be structured — not brochure-based.

Each property should be stored as structured fields, not documents.

Example Data Fields:

- Building name
- Micro-market
- Available area
- Rent
- CAM
- Floor
- Furnishing status
- Possession timeline
- Owner/operator
- Contact mapping
- Last verified timestamp

Core Output:
Matching between requirement and available properties.

Explore answers:

“What properties satisfy this requirement right now?”

B. ANALYTIC (Decision Intelligence Engine)

Primary Function:
Convert property and requirement data into actionable intelligence.

Key Technical Objectives:

- AI-assisted option generation
- Property comparison
- Automated proposal building
- Market insights

Core Features:
• AI proposal generator
• Automated comparison sheets
• Rental benchmarking
• Micro-market analytics
• PDF option builder
• Query-based property retrieval

Example User Prompt:
"Show 8,000–10,000 sq ft in Whitefield under ₹90 psf furnished."

System workflow:

1. Query requirement database
2. Match against availability database
3. Rank based on defined logic (budget, suitability, recency)
4. Generate formatted proposal
5. Check all availability by Chat/Voice Bots

Important:
AI is not the core — structured data is.
AI is a processing layer over verified data.

Analytic answers:

"Which options are best and how should they be presented?"

C. KONNECT (Transaction Workflow System)

Primary Function:
Deal management & collaboration workspace.

Each requirement or mandate becomes a **Deal Ticket**.

Core Objectives:

- Replace email + WhatsApp coordination
- Provide transparent transaction tracking
- Centralize documentation and negotiation
- Client can raise an RFP anonymous request.- Land lords / Brokers can Bid options

Core Components:
• Deal tickets
• Activity timeline
• Role-based access (broker / client / landlord)
• Document sharing (LOI, layouts, commercials)
• Comments & communication threads
• Negotiation tracking
• Stage tracking (Inquiry → Site Visit → Offer → Negotiation → Closure)

Deal Object Should Include:

- Linked requirement
- Linked properties
- Stakeholders
- Offer history
- Version tracking
- Communication log

Konnect answers:

"What is the current status of this deal?"

D. STUDIO (Media & Visualization Engine)

Primary Function:
Property visualization and verification.

Objectives:

- Allow remote understanding of space
- Attach media to property and deal
- Build trust without site visits

Core Components:
• Media asset storage
• HD image galleries
• Drone videos
• 360° virtual tours
• Future AR/VR compatibility

Each media file must be mapped to:
Property → Building → Unit → Deal (optional)

Studio answers:

"What does this property actually look like?"

4. Data Relationships (Very Important)

The platform revolves around three primary objects:

Requirement → Property → Deal

Flow:

1. A requirement is created
2. Properties are matched
3. Selected properties convert into a deal ticket
4. Media supports evaluation
5. Negotiation occurs within the deal

This relationship must be enforced in schema design.

5. User Roles

Minimum user roles:

- Occupier (client)
- Broker
- Landlord/Operator
- Admin
- Consultant (optional later)

Permissions must be role-based and deal-specific.

Example:
A landlord should only see deals they are invited to.

6. Design Philosophy

The system should behave like:

- CRM + Marketplace + Collaboration tool

Not like:

- a static listing website

Performance priority:
Speed and reliability over visual complexity.

Primary usage device:
Desktop first (brokers), mobile supportive (updates & communication).

7. Long-Term Extensibility

The system should allow future additions:

- RFP engine
- Digital LOI
- Lease documentation workflow
- Payments/booking tokens
- Portfolio analytics for developers

Hence, architecture should be modular and API-ready.

Final Understanding

The modules represent a transaction lifecycle:

Explore → Discovery
Analytic → Evaluation
Konnect → Execution
Studio → Verification

SFT is therefore not a feature product.
It is an integrated real estate transaction platform where data flows across modules and reduces friction in commercial leasing workflows.
